ALGEBRAIC PROPERTIES OF A FAMILY OF JACOBI POLYNOMIALS

JOHN CULLINAN, FARSHID HAJIR, ELIZABETH SELL

Abstract. The one-parameter family of polynomials $J_n(x, y) = \sum_{j=0}^{n} \binom{n+j}{j} x^j y^j$ is a subfamily of the two-parameter family of Jacobi polynomials. We prove that for each $n \geq 6$, the polynomial $J_n(x, y_0)$ is irreducible over $\mathbb{Q}$ for all but finitely many $y_0 \in \mathbb{Q}$. If $n$ is odd, then with the exception of a finite set of $y_0$, the Galois group of $J_n(x, y_0)$ is $S_n$; if $n$ is even, then the exceptional set is thin.

1. Introduction

For an integer $n \geq 1$ and complex parameters $\alpha, \beta$, define the polynomial

$$J_n^{(\alpha, \beta)}(x) := \sum_{j=0}^{n} \binom{n+\alpha}{n-j} \binom{n+\alpha+\beta+j}{j} x^j.$$ 

It is a slightly renormalized version of the Jacobi polynomial

$$P_n^{(\alpha, \beta)}(x) := J_n^{(\alpha, \beta)} \left( \frac{x-1}{2} \right).$$

In terms of the Gauss hypergeometric series

$$2F_1(a, b; -c | z) := \sum_{\nu=0}^{\infty} \frac{(a)_\nu (b)_\nu}{(c)_\nu} \frac{z^\nu}{\nu!}, \quad (a)_\nu := (a)(a+1) \cdots (a+\nu-1),$$

we have

$$P_n^{(\alpha, \beta)}(x) = 2F_1 \left( -n, n+\alpha + 1 + \beta; -, -\alpha + 1 \bigg| \frac{1-x}{2} \right).$$

Many important families of polynomials are obtained as specializations of Jacobi polynomials; among them we mention the Tchebicheff polynomials of the first ($T_n(x)$) and second kind ($U_n(x)$), the ultraspherical polynomials $P_n^{(\alpha, \alpha)}(x)$ (also called Gegenbauer polynomials), and the Legendre polynomials $P_n^{(0,0)}(x)$. Jacobi polynomials, together with the Generalized Laguerre polynomials

$$L_n^{(\alpha)}(x) := \sum_{j=0}^{n} \binom{n+\alpha}{n-j} \frac{(-x)^j}{j!},$$

and the Hermite polynomials

$$H_{2n}(x) := (-1)^n 2^n n! L_n^{(-1/2)}(x^2)$$

$$H_{2n+1}(x) := (-1)^n 2^{n+1} n! x L_n^{(1/2)}(x^2)$$

are the three classical families of orthogonal polynomials. Among all families of orthogonal families, they are distinguished by the fact that their derivatives are also members of the same family. Orthogonal polynomials play a very important role in analysis, mathematical physics, and representation theory.

The systematic study of algebraic properties of families of orthogonal polynomials was initiated by Schur. He showed, for instance, that the Hermite polynomials are irreducible over $\mathbb{Q}$ and determined their Galois groups [13].

The algebraic properties of some of the specializations of $P_n^{(\alpha, \beta)}(x)$ have been known for quite some time (e.g. $T_n$, $U_n$) whereas for others they appear to be quite difficult to establish (e.g. the Legendre polynomials

Key words and phrases. Hilbert irreducibility, orthogonal polynomials, Jacobi polynomial, Laguerre polynomial, rational point, Riemann-Hurwitz formula, simple cover, specialization.
Other hypergeometric families related to the theory of modular forms are specializations of Jacobi polynomials. For example, that the polynomials $F_{n}^{(1/2,1/3)}(x)$ are irreducible with Galois group $S_n$ equivalent to the conjecture introduced and studied by Mahlburg and Ono in [11]; these polynomials are on one hand related to traces of singular moduli via work of Kaneko-Zagier [9], and, up to simple factors, the supersingular polynomial for a prime $p$ where $n = [p/12]$ ([1],[2]).

In a recent work, Hajir-Wong [7] describe a method for studying the exceptional set for a one-parameter family $F_{n}^{(c)}(x) \in \mathbb{Q}[x,t]$ of polynomials, i.e. the set of $c \in \mathbb{Q}$ for which $F_{n}^{(c)}(x)$ is reducible. By applying their method, which is a combination of group theory and algebraic geometry, they showed that for each $n \geq 5$, for all but finitely many $c \in \mathbb{Q}$ the generalized Laguerre polynomial $L_{n}^{(c)}(x)$ is irreducible over $\mathbb{Q}$ and has Galois group $S_n$.

In the current work, we show a similar result for an arbitrary specialization at a point in $\mathbb{P}^{2}_{\mathbb{Q}}$ of the Jacobi polynomial $J_{n}(x,y) = (-1)^{n}J_{n}^{(-1-n,y+1)}(-x) = \sum_{j=0}^{n} \binom{y+j}{j} x^{j}$; more precisely:

**Theorem 1.** Let $n \geq 6$ be an integer and let $J_{n}(x,y) = \sum_{j=0}^{n} \binom{y+j}{j} x^{j}$. Then the polynomials $J_{n}(x,y_{0})$ are irreducible over $\mathbb{Q}$ for all but finitely many $y_{0} \in \mathbb{Q}$. Moreover, if $n$ is odd then the Galois group of $J_{n}(x,y_{0})$ is equal to $S_n$ for all but finitely many $y_{0} \in \mathbb{Q}$. If $n$ is even, then there is a thin set of $y_{0}$ for which the Galois group is $A_n$.

This result is far from effective, however, since the main tool for obtaining the result is Faltings’ theorem. We follow the strategy outlined in Hajir-Wong. We show that, as a polynomial over $\mathbb{Q}(y)$, $J_{n}(x,y)$ is irreducible with Galois group $S_n$. We then estimate the genus of the curve defined by the polynomial, as well as other minimal subfields in the Galois closure of its function field, allowing us to apply the theorem of Faltings to obtain the finitude of the exceptional set using a criterion described, for example, in Müller [12]. In addition we also obtain an exact expression for the genus of the curve $X_{1}$.

**Theorem 2.** Let $X_{1}$ be the algebraic curve defined by $J_{n}(x,y)$. Then the genus of the normalization of $X_{1}$ is $(n-1)/2$.

**Acknowledgements.** We would like to thank Siman Wong for useful discussions and the referee for many helpful comments and suggestions.

2. **The One-Parameter Family**

The linear change of variables

$$
\begin{align*}
  r &= -1 - n - \alpha \\
  s &= -1 - r + \beta
\end{align*}
$$

allows us to rewrite the Jacobi polynomials in terms of the parameters $r$ and $s$:

$$
P_{n}^{(r,s)}(x) := (-1)^{n}P_{n}^{(-1-n-r, r+s+1)}(-x) = \sum_{j=0}^{n} \binom{s+j}{j} x^{j}.
$$

Set $r = 0$ to get the one-parameter family (with $s = y$) given by:

$$
J_{n}(x,y) = P_{n}^{(0,y)}(x) = \sum_{j=0}^{n} \binom{y+j}{j} x^{j} = \sum_{j=0}^{n} (y+1) \cdots (y+j) \frac{x^{j}}{j!}.
$$

Let $\tilde{P}_{n}(x,y)$ be the reverse of $J_{n}(x,y)$ as a polynomial in $x$, i.e.

$$
\tilde{P}_{n}(x,y) := x^{n}J_{n}(1/x,y) = \sum_{j=0}^{n} \binom{y+j}{j} x^{n-j}.
$$

Clearly $\tilde{P}_{n}(x,y)$ and $J_{n}(x,y)$ have the same irreducibility and Galois-theoretic properties. With another linear change of variables we obtain a more convenient form of the polynomial, which we will work with for the rest of the paper:

$$
P_{n}(x,y) := (-1)^{n}\tilde{P}_{n}(-x, -y - 1) = \sum_{j=0}^{n} \binom{y}{j} x^{n-j}.
$$
Fix \( n \geq 6 \) and define the algebraic curve \( X_1 \subset \mathbb{P}^2 \) as the projective closure of the zero-set of \( P_n(x, y) \). Let \( X' \) denote the smooth curve corresponding to the Galois closure \( K' \) of \( P_n(x, y) \) over \( \mathbb{Q}(y) \). Following [7], we will show:

- For each \( n \geq 6 \), the polynomial \( P_n(x, y) \) has an irreducible \( \mathbb{Q} \)-rational specialization with Galois group \( S_n \).
- The genera of the intermediate subfields \( \mathbb{Q}(y) \subset E \subset K' \) are all \( \geq 2 \) with the exception of the fixed-field of \( A_n \) when \( n \) is even.

In fact, when \( n \) is even there will be a thin set of \( y_0 \) for which the specialized polynomial \( P_n(x, y_0) \) has Galois group \( A_n \). These steps will constitute a proof of Theorem 1 following the strategy outlined in [7].

3. Galois Properties of \( P_n(x, y) \)

In this section, we compute the Galois group of our polynomial \( P_n(x, y) \) over \( \mathbb{Q}(y) \). In a first draft of this paper, we did this by effectively finding an irreducible specialization with Galois group \( S_n \) over \( \mathbb{Q} \). We give a brief sketch of our original argument. To establish irreducibility, we compare the \( p \)-adic Newton polygons (for each \( p \mid n \)) of the \( P_n(x, y) \) to those of the truncated exponential polynomials \( e_n(x) \) which are known to be irreducible [5, lem. 2.7]. Once irreducibility is established, one can show that there exists a prime in the interval \( (n/2, n - 2) \) such that the \( \ell \)-adic Newton polygons of \( P_n(x, y) \) and \( e_n(x) \) coincide. By [6, thm. 2.2], the Galois group of \( P_n(x, y) \) then contains \( A_n \). To conclude that the Galois group is all of \( S_n \), it suffices to show the discriminant of \( P_n(x, y) \) is not a square. Effectivity is not required for the results of the paper, and the details are intricate, so we present a simpler proof. We would like to take this opportunity to thank the referee for providing us with this approach. We start by writing down the discriminant formula for \( P_n(x, y) \) as a polynomial in \( y \), which we get easily by specializing the formula for the discriminant of the Jacobi Polynomial [16, p. 143]:

\[
\text{disc}(P_n(x, y)) = \frac{(-1)^{n(n-1)/2}}{(n!)^{n-2}} (y)(y-n) \prod_{j=0}^{n} (y-j)^{n-2}.
\]

**Proposition 1.** For all \( n \geq 2 \) the polynomial \( P_n(x, y) \) is irreducible and has Galois group \( S_n \) over \( \mathbb{Q}(y) \).

**Proof.** It is easy to check that \( P_n(x, y) = \sum_{j=0}^{n} \binom{n}{j} x^{n-j} \) is Eisenstein at the place \( y \). This gives irreducibility.

For the Galois group \( G \), the discriminant formula above shows that specialization of \( P_n(x, y) \) at \( y_0 = 0, \ldots, n \) factors as \( P_n(x, y_0) = x^{n-k}(x+1)^k \) for all \( k = 0, \ldots, n \). Hence, the inertia subgroup of \( G \) contains permutations of cycle type \( (n-k, k) \) for all \( k = 0, \ldots, n \). When \( k = 1 \), this means \( G \) contains an \( (n-1) \)-cycle and hence is a 2-transitive subgroup of \( S_n \). If \( n \) is odd, then the \( (n-2) \)th power of an element of cycle type \( (n-2, 2) \) is a transposition. This implies \( G \) is all of \( S_n \).

If \( n \) is even, let \( n = 2^m u \) with \( u \) and odd integer. If \( u = 1 \), take \( k = 3 \), if \( u = 3 \) take \( k = 5 \), and if \( u \geq 7 \), take \( k = u - 2 \). This ensures that, except when \( n = 4 \) or \( 6 \), \( G \) contains a \( k \)-cycle with \( k \) in the range \([2, n/2]\). Thus \( G \) contains \( A_n \). Since \( G \) contains odd permutations, \( G \) is all of \( S_n \).

When \( n = 2, 4 \) or 6, the specialization \( y = 3, 8, \) or 11 (for example) yields a polynomial with Galois group \( S_2, S_4 \) or \( S_6 \), respectively. Since the Galois group of \( P_n(x, y_0) \) is a subgroup of the Galois group of \( P_n(x, y) \) for all good specializations, this means means \( P_2(x, y), P_4(x, y) \) and \( P_6(x, y) \) have Galois groups \( S_2, S_4 \) and \( S_6 \), respectively. This completes the proof. \( \square \)

4. A Genus Formula

The goal of this section is to prove Theorem 3 below on the genus of the curve \( X_1 \). We remark that \( X_1 \) is a singular curve, so by abuse of language, we refer to the genus of the normalization of \( X_1 \) as the genus of \( X_1 \). Let \( t_n : X_1 \to \mathbb{P}^1 \) be the projection-to-\( y \)-map. The discriminant formula above shows that the branch locus of \( t_n \) is given by

\[ B_n = \{0, \ldots, n\}. \]

The Riemann-Hurwitz formula implies

\[ 2g(X_1) - 2 = \deg(t_n)(-2) + \sum_{p \in X_1} (e_p - 1). \]
As in the previous section, one checks that \( P_n(x, \nu) = x^{n-\nu}(x+1)^\nu \) for all \( \nu \in B_n \). Moreover, one checks easily that there is no ramification at infinity (taking note of the fact that \( e_n(x) = \sum_{j=0}^{n} x^j/j! \) has discriminant \( \prod_{j=2}^{n} j^{-1} \)) by [13, p. 229] hence is separable. Thus, there are \( 2n \) points of \( X_1 \) ramified above \( \mathbf{P}^1 \), with the given ramification indices. The degree of \( \iota_n \) is \( n \), so altogether this gives

\[
g(X_1) = \frac{1}{2} \left(-2n + \frac{n(n+1)}{2} + \frac{n(n+1)}{2} - 2n\right) + 1 = \frac{1}{2} (n^2 - 3n + 2),
\]

and hence:

**Theorem 3.** Let \( g_n \) denote the geometric genus of the normalization of \( X_1 \). Then \( g_n = \binom{n-1}{2} \).

5. GENUS OF MAXIMAL SUBFIELDS

Recall the following notation: \( K' \) is the Galois closure of the field \( K_1/Q(y) \) which is the function field of the covering \( X_1/\mathbf{P}^1 \) where \( X_1 \) is given by the model \( P_n(x, y) = 0 \). We have shown in Section 3 that the Galois group of \( K'/Q(y) \) is \( S_n \). We adopt the notation of [7]. Let \( E \) be an intermediate field of \( K'/Q(y) \), let \( E = \text{Gal}(K'/E) \), and let \( X_E \) be the smooth curve with function field \( E \). Following [7, thm. 3], we will now show that if \( P_n(x, y) \) is reducible over \( E \), then the genus of \( X_E \) is greater than 1. We will achieve this by showing that the genera of the *minimal* subfields of \( K' \) over which \( P_n(x, y) \) is reducible (corresponding to maximal subgroups of \( S_n \)) are each greater than 1.

Recall the definition of simple branch point from [7, def. 2], and recall our notation: \( B_n = \{0, \ldots, n\} \) is the branch locus of the projection-to-y map \( \iota_n : X_1 \rightarrow \mathbf{P}^1 \). Consequently:

**Lemma 1.** The branch points \( \nu = 0, 1, (n-1), \) and \( n \) are simple of index \( n, n-1, n-1, \) and \( n \), respectively.

Now we estimate the genera of the intermediate subfields. Our strategy is as follows. We start with the maximal subgroups of \( S_n \) other than \( A_n \); they will all be shown to have fixed field of genus exceeding 1. For even \( n \), the fixed field of \( A_n \) has genus 0 but it turns out that \( P_n(x, y) \) is irreducible over that field. It will then remain to show that the fixed fields of the maximal subgroups of \( A_n \) all have genus exceeding 1.

Since the rest of the paper involves computations with the maximal subgroups of \( S_n \), we appeal to the structure theorem of [10]: if \( G \) is \( A_n \) or \( S_n \), and \( E \) is any maximal subgroup of \( G \) with \( E \neq A_n \), then \( E \) satisfies one of the following:

(a) \( E = (S_m \times S_k) \cap G \), with \( n = m+k \) and \( m \neq k \).
(b) \( E = (S_m \wr S_k) \cap G \), with \( n = mk \), \( m > 1 \) and \( k > 1 \).
(c) \( E = AGL_n(\mathbf{F}_p) \cap G \), with \( n = p^k \) and \( p \) prime.
(d) \( E = (T^k : (Out T \times S_k)) \cap G \), with \( T \) a non-abelian simple group, \( k \geq 2 \) and \( n = \#T^{k-1} \).
(e) \( E = (S_m \wr S_k) \cap G \), with \( n = m+k \), \( m \geq 5 \) and \( k > 1 \), excluding the case where \( E \) is imprimitive.
(f) \( T < E \leq Aut T \), with \( T \) a non-abelian simple group, \( T \neq A_n \), and \( E \) primitive.

For completeness, we recall the notion of a primitive group [4, p. 12]. Let \( G \) be a group acting transitively on a set \( \Omega \). A non-empty subset \( \Delta \) of \( \Omega \) is called a block for \( G \) if for each \( x \in \Omega \) either \( \Delta^x = \Delta \) or \( \Delta^x \cap \Delta = \emptyset \). The group \( G \) is called primitive if it has no nontrivial blocks. The groups of type (a) and (b) are imprimitive, while types (c)-(f) are primitive.

**Proposition 2.** Let \( n \geq 6 \). If \( E \) is a maximal subgroup of \( S_n \) other than \( A_n \), with corresponding fixed-field \( E \), then \( g(X_E) > 1 \).

**Proof.** Let \( V = \{0, 1, n-1, n\} \) be the set of simple branch points of \( \iota_n : X_1 \rightarrow \mathbf{P}^1 \). Following [7], let \( d(k) \) be the least prime divisor of the positive integer \( k \), and define \( c_1(\nu) \) as in [7, defn. 1]. Every \( \nu \in V \) is simple, so by [7, lem. 6], \( c_1(\nu) \) is easily computed:

\[
c_1(\nu) = \frac{\# \text{ of } e_{\nu}\text{-cycles in } E}{\#E} \times e_\nu(n - e_\nu)! < e_\nu(n - e_\nu)!.
\]

We now employ the genus estimate of [7, (4.1)]

\[
g(X_E) \geq 1 + \frac{|S_n : E|}{2} \left(-2 + \sum_{\nu \in V} \left(1 - \frac{1}{4d(e_\nu)}\right)\right) = \frac{1}{2} \sum_{\nu \in V} c_1(\nu) \left(1 - \frac{1}{d(e_\nu)}\right).
\]
For each $\nu \in V$, the ramification index $e_\nu$ is either $n$ or $n - 1$. In particular, two of the four $e_\nu$ are even and for those, $d(e_\nu) = 2$; for the others $d(e_\nu) \geq 3$. Let $N$ be the odd element of the set $\{n, n - 1\}$. Then
\[
\left(-2 + \sum_{\nu \in V} \left(1 - \frac{1}{d(e_\nu)}\right)\right) = -2 + 4 - \frac{1}{2} - \frac{2}{d(N)} \geq 1 - \frac{2}{3} = \frac{1}{3}.
\]
We now split the rest of the proof into three cases based on the structure of the maximal subgroup $E$.

**Case 1 – imprimitive wreath products**

Here we must take $n \geq 4$. The maximal imprimitive wreath products contain no $n$ or $(n - 1)$-cycles, hence $c_1(\nu) = 0$ for all $\nu \in V$. The genus estimate for $E = S_j \wr S_{n/j}$ is therefore
\[
g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{n!}{(j!)^n/(n/j)!},
\]
which is greater than 1.

**Case 2 – intransitive subgroups**

Take $n \geq 3$. None of the subgroups $S_j \times S_{n-j}$ will contain an $n$-cycle, and will only contain an $(n-1)$-cycle when $j = 1$. Hence for $j = 2, \ldots, \lfloor \frac{n-1}{2} \rfloor$, the genus estimate is
\[
g(X_E) \geq 1 + \frac{n!}{j!(n-j)!},
\]
which is greater than 1. When $j = 1$, the subgroup $S_{n-1}$ of $S_n$ contains $(n-2)!$ cycles of length $(n-1)$. Hence the genus estimate becomes
\[
g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{n!}{(n-1)!} - \frac{1}{2} \cdot \frac{(n-2)!}{(n-1)!} \cdot (n-1)! \cdot (1 - \frac{1}{3}) = \frac{n}{6} + \frac{1}{3},
\]
which is greater than 1 when $n \geq 5$.

**Case 3 – primitive subgroups**

If $E$ is a proper primitive subgroup of $S_n$ other than $A_n$, then Bochert’s theorem [4, p. 79] bounds its index in $S_n$:
\[
[S_n : E] \geq \lfloor \frac{n + 1}{2} \rfloor!.
\]
The basic estimate $(1 - 1/d(e_\nu)) \leq 1 - 1/n$ gives us
\[
g(X_E) \geq 1 + \frac{1}{6} \cdot \left\lfloor \frac{n + 1}{2} \right\rfloor! - \frac{1}{2} \left(1 - \frac{1}{n}\right) \sum_{\nu \in V} c_1(\nu)
\geq 1 + \frac{1}{6} \cdot \left\lfloor \frac{n + 1}{2} \right\rfloor! - \frac{1}{2} \left(1 - \frac{1}{n}\right) (n + (n-1) + (n-1) + n)
= 1 + \frac{1}{6} \cdot \left\lfloor \frac{n + 1}{2} \right\rfloor! - \frac{2n - 3 + \frac{1}{n}}{2}.
\]
This gives $g(X_E) > 1$ when $n \geq 9$. For a more refined estimate, we investigate the primitive subgroups of the symmetric groups.

Let $n = 8$. Then the maximal primitive subgroups of $S_8$ other than $A_8$ are $2^3 \cdot \text{PSL}_2(F_7)$ and $\text{PGL}_2(F_7)$. The group $2^3 \cdot \text{PSL}_2(F_7)$ has order 1344, contains 384 7-cycles, and no 8-cycles. This gives
\[
g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{8!}{1344} - \frac{1}{2} \left(1 - \frac{1}{8}\right) \left(0 + 0 + \frac{384}{1344} \cdot 7 \cdot 1! + \frac{384}{1344} \cdot 7 \cdot 1!\right) = \frac{17}{4}.
\]
The order of $\text{PGL}_2(\mathbb{F}_7)$ is 336 and it contains 48 7-cycles and 84 8-cycles, hence

$$g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{8!}{336} - \frac{1}{2} \left(1 - \frac{1}{8}\right) \left(2 \cdot \frac{48}{336} \cdot 7 \cdot 1! + 2 \cdot \frac{84}{336} \cdot 8 \cdot 0! \right) = \frac{147}{8}.\]

Now take $n = 7$. There is a unique maximal primitive subgroup of $S_7$ other than $A_7$, namely $\text{PSL}_2(\mathbb{F}_7)$. It contains 48 7-cycles and no 6-cycles. Therefore

$$g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{7!}{168} - \frac{1}{2} \left(1 - \frac{1}{7}\right) \left(2 \cdot \frac{48}{168} \cdot 7 \cdot 1! \right) = \frac{30}{7}.\]

The group $S_6$ has a unique maximal primitive subgroup other than $A_6$, namely $\text{PGL}_2(\mathbb{F}_5)$. But $\text{PGL}_2(\mathbb{F}_5) \simeq S_5 \times S_1$ is an intransitive direct-product subgroup of $S_6$ and hence was already analyzed. This completes the proof of the Proposition.

**Remark.** When $n = 5$, the unique maximal primitive subgroup of $S_5$ other than $A_5$ is the Frobenius group $F_{20}$ of order 20. It contains 10 4-cycles and 4 5-cycles. Using the exact values for the $d(e_n)$ yields

$$g(X_E) \geq 1 + \frac{1}{2} \cdot \frac{5!}{20} \left(-2 + 2 \cdot \left(1 - \frac{1}{d(5)}\right) + 2 \cdot \left(1 - \frac{1}{d(4)}\right)\right) - \frac{1}{2} \left(2 \cdot \frac{10}{20} \cdot 4 \cdot 1! \cdot \left(1 - \frac{1}{d(4)}\right) + 2 \cdot \frac{5}{20} \cdot 5 \cdot 0! \cdot \left(1 - \frac{1}{d(5)}\right)\right) = \frac{5}{4},$$

so a more detailed analysis would be required determine whether the genus of $X_E$ is greater than 1.

The unique index-2 subgroup $A_n$ of $S_n$ corresponds to the field $\mathbb{Q}(y, \Delta_n)$ where $\Delta_n := \sqrt{\text{disc}(P_n(x,y))}$. We have two different results based on whether $n$ is even or odd.

**Lemma 2.** Let $C_n$ be the curve corresponding to the degree-2 field extension $\mathbb{Q}(y, \Delta_n)/\mathbb{Q}(y)$. If $n$ is odd, then $C_n$ has genus $\left\lfloor \frac{n-2}{2} \right\rfloor$; if $n$ is even, then $C_n$ has genus 0. In particular, for odd $n \geq 7$ and $E = A_n$, we have $g(X_E) > 1$.

**Proof.** Recall the discriminant of $P_n(x,y)$ as a polynomial in $y$ is given by

$$\text{disc}(P_n(x,y)) = \pm \frac{1}{(n!)^{n-2}} y(y - n) \prod_{j=1}^{n-1} (y - j)^{n-2},$$

where $\pm = (-1)^{n(n-1)/2}$. When $n$ is even the square-free part of the discriminant is $\pm y(y - n)$, hence a model for $C$ is given by

$$z^2 = \pm y(y - n),$$

which defines a smooth curve of genus 0. If $n$ is odd, the square-free part of the discriminant is $\frac{\pm 1}{n!} \prod_{j=1}^{n-1} (y - j)$, and a model for $C_n$ is given by

$$z^2 = \pm \frac{1}{n!} \prod_{j=1}^{n-1} (y - j).$$

Therefore $C_n$ is a hyperelliptic curve of genus $\left\lfloor \frac{n-2}{2} \right\rfloor$. \hfill $\square$

We now take up the case where $n$ is even, so that the genus of the fixed-field of $A_n$ is always 0. By [7, Prop. 3], it suffices to consider the maximal proper subgroups of $A_n$, which are described in the structure theorem above. The groups of type (a) and (b) are imprimitive, while types (c)-(f) are primitive. None of the imprimitive groups are contained in $A_n$, so their indices in $S_n$ are as follows:

$$[S_n : E \cap A_n] = \begin{cases} 2 \cdot \binom{n}{k}^2 \frac{n!}{j^n!} & \text{if } E = S_m \times S_k \\ 2 \cdot \binom{n}{j}^2 \frac{n!}{j^n!} \frac{n!}{(n/j)!} & \text{if } E = S_j \times S_{n/j}. \end{cases}$$

**Proposition 3.** Let $n \geq 6$ be an even integer and $E$ a maximal proper subgroup of $A_n$. Then the genus of $X_E$ is greater than 1.
Proof. As in the proof of Proposition 2 we split the proof into three cases according to the structure of $E$.

**Case 1 – imprimitive wreath products**

In this case we require $n \geq 4$ and take $E = (S_j \wr S_{n/j}) \cap A_n$, so that $[S_n : E] = \frac{2 \cdot n!}{3^{n/j}(n/j)!}$. The subgroup $S_j \wr S_{n/j}$ of $S_n$ contains no $n$ or $(n-1)$-cycles so that $c_1(\nu) = 0$ for all $\nu \in V$. Hence $g(X_E) > 1$.

**Case 2 – intransitive subgroups**

Here we take $n \geq 4$ (recall $n$ is even) and consider the subgroups $E = (S_j \times S_{n-j}) \cap A_n$. None of the $E$ contain an $n$-cycle, and only $S_j \times S_{n-1}$ contains an $(n-1)$-cycle. When $j = 1$ we have $E = (S_1 \times S_{n-1}) \cap A_n \simeq A_{n-1}$. The order of $A_{n-1}$ is $(n-1)!/2$ and it contains $(n-2)!$ $(n-1)$-cycles. Altogether this gives:

$$
g(X_E) \geq 1 + \frac{1}{6} \cdot \frac{n!}{(n-1)!/2} - \frac{1}{2} \left( 0 + 0 + 2 \cdot \left( 1 - \frac{1}{n} \right) \cdot \left( \frac{(n-2)!}{(n-1)!/2} \cdot (n-1) \cdot 1 \right) \right) = 2n - 1 + \frac{2}{n},$$

which is greater than 1.

**Case 3 – primitive subgroups**

If $E$ is a primitive subgroup of $A_n$, then it is automatically a primitive subgroup of $S_n$, and hence is contained in some maximal primitive subgroup of $S_n$. All the maximal primitive subgroups of $S_n$ (other than $A_n$) have been analyzed in Proposition 2. Moreover, before the proof of this proposition we noted that it suffices to consider the maximal proper subgroups of $A_n$, so we need not estimate the genus of the fixed-field coming from $A_n$ itself. This completes the proof. \qed
